Assignment 2 COS 212

Department of Computer Science Deadline: 8 April 2019 at 12:00pm

Objectives:

- Implementing a double threaded binary search tree.
- Implementing a double threaded tree balanced using the DSW algorithm.

General instructions:

- This assignment should be completed individually, **no group effort** is allowed.
- Only the output of your Java program will be evaluated.
- Your code may be inspected to ensure that you've followed the instructions.
- Be ready to upload your assignment tasks well before the deadline, as no extensions will be granted.
- You are NOT allowed to import any Java packages. Doing so you will receive a mark of 0. You must provide your own implementation of any additional data structures that you require.
- If your code does not compile you will be awarded a mark of 0.
- You will be afforded three opportunities to upload your submissions for automarking.

Plagiarism:

The Department of Computer Science regards plagiarism as a serious offence. Your code will be subject to plagiarism checks and appropriate action will be taken against offending parties. You may also refer to the Library's website at www.library.up.ac.za/plagiarism/index.htm for more information.

After completing this assignment:

Upon successful completion of this assignment you will have implemented your own double threaded binary search tree, as well as a double threaded tree balanced using the DSW algorithm in Java.

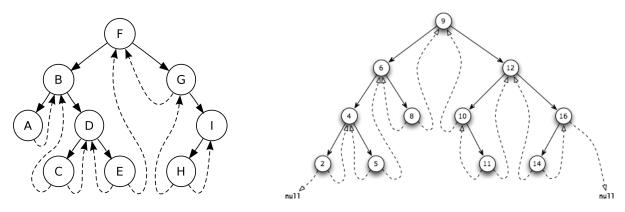

Task 1

Download the archive assignment2Code.tar.gz and untar it in an appropriate directory. The archive contains the following files:

- DTNode.java
- DoubleThreadedBST.java
- DoubleThreadedDSW.java
- Tester.java

These files contain partial classes that you must complete. For Task 1, you will have to implement the DTNode and DoubleThreadedBST classes.

- Class DTNode describes a double threaded node. A double threaded node is a node that re-uses
 unused left and right data fields as shortcuts to the inorder predecessor and successor nodes,
 respectively, allowing for efficient inorder tree traversal that requires neither recursion nor a
 stack. It is also possible to implement non-recursive preorder and postorder traversals using the
 same threads.
- Class DoubleThreadedBST describes a double threaded binary search tree, i.e. a binary search tree where every node is a double threaded node. Inserting into a double threaded BST is similar to inserting into a single threaded BST, with the difference that both the left and the right threads have to be maintained. The same applies to other operations such as deletion. Here are two examples of double threaded BSTs:

One benefit of double threading is that efficient inorder traversal can be performed left to right (ascending order) or right to left (descending order).

Implement all the functions specified in the given classes. You are not allowed to modify method signatures or class names. You are allowed to add extra methods and/or member data fields as necessary.

Test your code thoroughly before proceeding to the next task.

Task 2

For this task, you will extend your double threaded tree to allow for periodic rebalancing using the DSW algorithm. The DSW algorithm restructures an arbitrary binary search tree into a perfectly balanced binary search tree, thus ensuring the tree is efficient to search at all times. A double threaded tree combined with the DSW algorithm allows non-recursive traversal with a perfectly balanced tree structure.

Class DoubleThreadedDSW describes a double threaded tree to which you have to add the DSW algorithm. All methods of DoubleThreadedBST are inherited, but some may have to be overridden to

suit the DSW algorithm's needs. Note that threads will have to be **adjusted accordingly** during the re-balancing. It is your task to devise an algorithm that will adjust the threads correctly.

HINT: Before jumping to the code, understand the process visually by drawing threaded trees on paper, performing various rotations on them, and observing how the existing threads must change. If you understand the process, you can write an algorithm in pseudocode to express it. If you can write the pseudocode, you can translate it to Java!

Submission Instructions:

You must create your own makefile, in which your code should be compiled with the following command:

javac *.java

Your makefile should also include a run rule which will execute your code if typed on the command line as in make run.

For your submission, you must tar your Java code together with the makefile, with no folders/subfolders. Your Java archive should be named sXXXass2.tar.gz, where XXX is your student/staff number. Separate upload links are provided for the two tasks. Each link grants 3 uploads. Every upload is a marking opportunity, do not use it to test your code. Test the code thoroughly, with multiple test cases, before submitting it for marking.

Good luck!
